

## Brew day sheet- Extract I.P.A 11 Litre

This brew day sheet provides instructions which are specific to your recipe pack. Points in this Brew day sheet which are numbered and marked in **bold** are further explained in the brewing guide.

### Steeping

Prepare some heated water to steep the grains for 20 minutes hour. It helps to have the grains in muslin cloth so they can be easily removed after this stage.

	Recommended	Actual	Record steeping Time
<b>1. Steeping Water volume:</b> The starting amount of heated water.	<b>A:</b> 6 Litres		Started:
<b>2. Steeping water temperature:</b> The Ideal temperature of the heated water prior to mixing in the steeping grains.	66°C		Finished:

Maintain the mash temperature for 20 minutes. Remove the grains when this time is complete

Meanwhile boil and cool 7 litres of tap water which you will need to top up your fermenter. If you have used a smaller pot and a smaller quantity of water to boil and steep, you'll need more boiled cooled water to make 11 litres for the fermenter.

### Boiling

Bring the heat back up to the boil and maintain a rolling boil.

	Recommended	Actual
<b>3. Boil Length:</b> Length of time the wort is boiled for.	60 minutes	

### Hop Additions

Weigh out hops from your labelled hop packets according to the recommended weights. Add these hops to the boiling wort at the recommended time intervals from the start of the boil to provide bitterness, aroma, and flavour.

<b>4. Hop Pack</b>	Weight	Recommended boil time	Time added
B	10g	60 minutes	
A	10g	60 minutes	
B	10g	7 minutes	
A	10g	7 minutes	
B	10g	Dry Hop 4 days	
A	10g	Dry Hop 4 days	

### Cooling

Rapidly chill the wort by placing the pot in a sink of iced water, or use a 'wort chiller'. Cool the wort to 18-23°C and transfer it to a **sanitised** fermentation vessel. Dry hopping should be undertaken once fermentation is complete 4 days prior to packaging.

### Fermentation

Once wort is collected in a **sanitised** fermenter check the temperature is between (18-23 °C) and record a hydrometer reading. If your hydrometer reading is higher than the recommended original gravity, you can adjust this to match the recipe by adding water. Pitch the yeast, seal the fermenter and add an airlock or blow off tube. Allow it to ferment at 18-23°C for 7 to 10 days or until fermentation looks complete and is confirmed with stable hydrometer readings over a 24 hour period (see below).

**Targets**

	Desired	Actual
<b>5. Volume Collected</b> (Volume in the fermentation vessel)	11 Litres	
<b>6. Original Gravity</b> (Hydrometer reading before adding yeast)	1.065	
<b>7. Finishing Gravity</b> (Hydrometer reading after fermentation)	1.014	
<b>8. Calculate the ABV</b>	6.6%	

**Bottling and Priming**

Use your hydrometer to check fermentation has finished. Two consecutive readings 24 hours apart with no movement in readings will confirm your beer has finished fermenting. Carefully siphon the beer off the sediment directly into bottles, keg, barrel or secondary bottling vessel.

	Recommended	Amount used
<b>9. Bulk priming sugar</b>	68g	
<b>10. OR sugar per 500 ml bottle</b>	2g (<half teaspoon)	

After bottling, kegging, or putting in a barrel, store at room temperature for 10 days to carbonate. Condition at room temperature or cooler (4-23 °C) for another 3 weeks before drinking.

**Customisation options**

Description	What to add (per gallon)	When to add
New England IPA yeast	Enhance fruitiness from the yeast with Yeastbay Vermont Ale, or WLP095 Burlington Ale.	At the start of fermentation, replace the pack yeast with one of the suggestions.
Double dry-hopped - For a seriously punchy citrus aroma.	50g Citra/Amarillo/Azacca.	Dry hop after fermentation for 4 days.
